

ThermalAtlas

User Manual

Overview

Lightweight, privacy-friendly menu bar app for real CPU, GPU and SSD temperatures. No telemetry, accounts or hardware control.

First launch

Open the DMG and drag ThermalAtlas to Applications. If required, confirm Gatekeeper with right-click > Open. If macOS asks for permission to access required system/sensor data on first launch, allow it or temperature readings may be unavailable.

Interface

Readings

CPU, GPU, internal SSD and external SSD are shown separately. Missing real values are not estimated.

Refresh

Regular sensor refresh every two seconds. The menu bar shows the highest available temperature.

Theme

Choose Classic, Liquid Glass, Aurora or Ember.

Buttons

Waveform: open macOS Activity Monitor. Power: quit ThermalAtlas completely.

Sensors, Privacy & Notes

Sensors

CPU/GPU are read-only through Apple-silicon SMC/IOKit. SSD temperatures are used only when macOS/controller exposes real SMART values.

Not available

If a real sensor value is missing, ThermalAtlas deliberately shows "Not available" rather than estimating.

Privacy

No accounts, telemetry, analytics services or cloud sync. Temperature readings are not stored permanently.

Resources

The app is intentionally lightweight; the permanent Liquid Glass glow animation was removed. Exact CPU/GPU usage claims should wait for runtime tests.
